1(i)	$(8)\int \frac{1}{16+x^2}\,dx = (8)\left(\frac{1}{4}\arctan\left(\frac{x}{4}\right)\right)$	Obtains ...arctan (kx) Allow k = 1	M1
	$2\left[\arctan\left(\frac{x}{4}\right)\right]_4^{4\sqrt{3}} = 2(\arctan\sqrt{3} - \arctan 1) = ...$	Substitutes the given limits, subtracts either way round and obtains a value (could be a decimal). The substitution does not need to be seen explicitly and may be implied by their value.	**d**M1
	$\frac{\pi}{6}$ or $p = \frac{1}{6}$ Correct exact value (or value for p) Accept equivalent exact expressions e.g. $\frac{2\pi}{12}$ or $p = \frac{2}{12}$ and isw if necessary.		A1
			(3)
(ii)	$2\int \frac{1}{\sqrt{9-4x^2}}\,dx = 2\left(\frac{1}{2}\arcsin\frac{2x}{3}\right)\left(\text{or e.g. } \arcsin\frac{x}{3/2}\right)$ **M1**: Obtains ...arcsin (kx). Allow k = 1 so allow just arcsin x. **A1**: Fully correct integration but allow unsimplified as above		M1 A1
	$\left[\arcsin\left(\frac{2x}{3}\right)\right]_{\frac{3}{4}}^{k} = \arcsin\left(\frac{2k}{3}\right) - \arcsin\left(\frac{1}{2}\right) = \frac{\pi}{12}$ $\Rightarrow \arcsin\left(\frac{2k}{3}\right) = \frac{\pi}{12} + \frac{\pi}{6} \Rightarrow \frac{2k}{3} = \sin\left(\frac{\pi}{4}\right) \Rightarrow \frac{2k}{3} = \frac{\sqrt{2}}{2} \Rightarrow k = ...$ Substitutes the given limits, subtracts either way round, sets = $\frac{\pi}{12}$, uses $\arcsin\left(\frac{1}{2}\right) = \frac{\pi}{6}$ and the correct **order** of operations condoning sign errors only to reach a value for k e.g. $\pm\alpha\left(\arcsin\left(\frac{2k}{3}\right) - \frac{\pi}{6}\right) = \frac{\pi}{12} \Rightarrow \arcsin\left(\frac{2k}{3}\right) = \frac{\pi}{12\alpha} \pm \frac{\pi}{6} \Rightarrow k = \frac{3\sin\left(\frac{\pi}{12\alpha} \pm \frac{\pi}{6}\right)}{2}$ Note that k may be inexact (decimal) or may be in terms of "sin" but must have a simplified argument e.g. $k = \frac{3\sin\left(\frac{\pi}{4}\right)}{2}$		**d**M1
	$k = \frac{3\sqrt{2}}{4}$ or exact equivalent e.g., $\frac{3}{2\sqrt{2}}$ Note that a common incorrect answer is $k = \frac{3}{2}\sin\left(\frac{5\pi}{24}\right)(= 0.913...)$ which comes from an incorrect integral of $2\arcsin\left(\frac{2x}{3}\right)$ (generally scoring 1010) Condone $x = \frac{3\sqrt{2}}{4}$		A1

Note that some candidates go straight into solving $|\mathbf{M}-\lambda\mathbf{I}|=0$ e.g.

$$\begin{vmatrix} -\lambda & -1 & 3 \\ -1 & 4-\lambda & -1 \\ 3 & -1 & -\lambda \end{vmatrix}=0 \Rightarrow -\lambda\left(\lambda(\lambda-4)-1\right)+3+\lambda+3\left(1-3(4-\lambda)\right)=0$$

$$\Rightarrow \lambda^3-4\lambda^2-11\lambda+30=0 \Rightarrow \lambda=-3,\ 5,\ 2$$

If this is all they do then the B mark in (c) can be awarded for $\lambda = 2$

The other marks in the question are available for the appropriate work.

5(a) **Way 1** **From LHS**	$\left(1-\text{sech}^2 x=\right)1-\left(\dfrac{2}{e^x+e^{-x}}\right)^2$	Replaces sech x with correct expression in terms of exponentials	B1
	$=\dfrac{\left(e^x+e^{-x}\right)^2-4}{\left(e^x+e^{-x}\right)^2}=\dfrac{e^{2x}+2+e^{-2x}-4}{\left(e^x+e^{-x}\right)^2}$	Expresses as a single fraction (or 2 fractions with the same denominator) and expands numerator	M1
	$=\dfrac{\left(e^x-e^{-x}\right)^2}{\left(e^x+e^{-x}\right)^2}=\tanh^2 x$	Fully correct proof	A1*
Way 2 **Diff. of 2 squares**	$1-\text{sech}^2 x=(1+\text{sech}\, x)(1-\text{sech}\, x)=\left(1+\dfrac{2}{e^x+e^{-x}}\right)\left(1-\dfrac{2}{e^x+e^{-x}}\right)$ Uses difference of two squares and replaces sech x with correct expression in terms of exponentials		B1
	$=\left(\dfrac{e^x+e^{-x}+2}{e^x+e^{-x}}\right)\left(\dfrac{e^x+e^{-x}-2}{e^x+e^{-x}}\right)=\dfrac{e^{2x}+1-2e^x+1+e^{-2x}-2e^{-x}+2e^x+2e^{-x}-4}{\left(e^x+e^{-x}\right)^2}$ Expresses as a single fraction and expands numerator		M1
	$=\dfrac{e^{2x}-2+e^{-2x}}{\left(e^x+e^{-x}\right)^2}=\dfrac{\left(e^x-e^{-x}\right)^2}{\left(e^x+e^{-x}\right)^2}=\tanh^2 x$	Fully correct proof	A1*
Way 3 **From RHS**	$\left(\tanh^2 x=\right)\dfrac{\left(e^x-e^{-x}\right)^2}{\left(e^x+e^{-x}\right)^2}$	Replaces tanh x with correct expression in terms of exponentials	B1
	$=\dfrac{e^{2x}-2+e^{-2x}}{\left(e^x+e^{-x}\right)^2}=\dfrac{e^{2x}+2+e^{-2x}}{\left(e^x+e^{-x}\right)^2}-\dfrac{4}{\left(e^x+e^{-x}\right)^2}$ Expands numerator and splits into two fractions		M1
	$=\dfrac{\left(e^x+e^{-x}\right)^2}{\left(e^x+e^{-x}\right)^2}-\left(\dfrac{2}{e^x+e^{-x}}\right)^2=1-\text{sech}^2 x$	Fully correct proof	A1*
			(3)

Allow "meet in the middle" approaches as long as a conclusion is given e.g. lhs = rhs

Example:

$$rhs=\tanh^2 x=\frac{\left(e^{2x}-1\right)^2}{\left(e^{2x}+1\right)^2}\quad\text{or}\quad lhs=1-\text{sech}^2 x=1-\left(\frac{2}{e^x+e^{-x}}\right)^2$$

B1: Replaces tanh x or sech x with a correct expression in terms of exponentials

$$\frac{\left(e^{2x}-1\right)^2}{\left(e^{2x}+1\right)^2}=\frac{e^{4x}-2e^{2x}+1}{e^{4x}+2e^{2x}+1}\quad\text{and}\quad 1-\left(\frac{2}{e^x+e^{-x}}\right)^2=\frac{\left(e^x+e^{-x}\right)^2-4}{\left(e^x+e^{-x}\right)^2}=\frac{e^{2x}-2+e^{-2x}}{e^{2x}+2+e^{-2x}}$$

M1: Makes progress by e.g. removing brackets on *rhs* and expressing *lhs* as a single fraction and expands numerator

$$\frac{e^{2x}-2+e^{-2x}}{e^{2x}+2+e^{-2x}}=\frac{e^{4x}-2e^{2x}+1}{e^{4x}+2e^{2x}+1}\Rightarrow 1-\text{sech}^2 x=\tanh^2 x$$

A1: Correct proof and (minimal) conclusion e.g. "= rhs" etc.

$$1-\operatorname{sech}^2 x = 1-\left(\frac{2}{e^x+e^{-x}}\right)^2 = \frac{e^{2x}+2+e^{-2x}-4}{\left(e^x+e^{-x}\right)^2} = \frac{e^{2x}+e^{-2x}-2}{e^{2x}+e^{-2x}+2} = \frac{\sinh^2 x}{\cosh^2 x} = \tanh^2 x$$

$$1-\operatorname{sech}^2 x = 1-\left(\frac{2}{e^x+e^{-x}}\right)^2 = \frac{e^{2x}+2+e^{-2x}-4}{\left(e^x+e^{-x}\right)^2} = \frac{e^{2x}+e^{-2x}-2}{e^{2x}+e^{-2x}+2} = \tanh^2 x$$

Both score B1M1A0 as we would need to see numerators and denominators factorised.

Note that we will allow an equivalent identity to be proved by exponentials and the given identity deduced e.g.

$$\cosh^2 x - \sinh^2 x = \left(\frac{e^x+e^{-x}}{2}\right)^2 - \left(\frac{e^x-e^{-x}}{2}\right)^2$$

B1: Correct exponential form seen for cosh or sinh used

$$= \frac{e^{2x}}{4}+\frac{1}{2}+\frac{e^{-2x}}{4}-\frac{e^{2x}}{4}+\frac{1}{2}-\frac{e^{-2x}}{4} = 1$$

M1: Expands and collects terms

$$\Rightarrow \cosh^2 x - \sinh^2 x = 1 \Rightarrow 1-\operatorname{sech}^2 x = \tanh^2 x$$

A1*: Fully correct work leading to the correct identity

$$I_5 = I_3 - \frac{\left(\frac{3}{5}\right)^{5-1}}{3(5-1)}$$

The second **M** mark would also score at this point as in the main scheme for integrating $\tanh 3x$ to obtain $q\ln(\cosh rx)$ oe e.g. $q\ln(\text{sech } rx)$

$$\left[\frac{1}{3}\ln\left(\cosh 3x\right) + \frac{1}{6}\text{sech}^2 3x\right]_0^{\frac{1}{3}\ln 2} - \frac{\left(\frac{3}{5}\right)^{5-1}}{3(5-1)} = \frac{1}{3}\ln\frac{5}{4} + \frac{1}{6} \times \frac{16}{25} - \frac{1}{6} - \frac{27}{2500}$$
